Semi-Commutators

A commutator is generally defined as: $[A, B] = AB \cdot B'A'$, where A and B are sequences of moves, representing permutations of pieces on a cube.

It has been proved that A_n , the alternating group on n items, $n \geq 5$, consists *entirely* of commutators, so that any permutation of A_n can be represented by a commutator or by a product of commutators, where the two representations are strictly equivalent, at least from a theoretical standpoint.

It may, however, be of interest to find products of commutators that give short sequences of moves, at least for products of a few commutators. For this to happen, there must be move cancellation between consecutive commutators. When a *maximum* number of moves have been cancelled out this way, a commutator-like expression is obtained, which can be called a *semi-commutator*. The structure of a semi-commutator depends on a number of *variables* and on the *direction* of enclosing brackets. Examples below are given for 3 and 4 variables and can be easily extended to a higher number of variables.

3 variables

Expressions of semi-commutators

$[X, YZ] = X \cdot YZ \cdot X' \cdot Z'Y'$ (commutator)

$[X, YZ] = X \cdot YZ \cdot X' \cdot Y'Z'$ (semi-commutator)

$]XY, Z[= XY \cdot Z \cdot X'Y' \cdot Z'$ (semi-commutator)

$]XY, Z[= [X, YZ]$

Semi-commutators as products of 2 commutators (move cancellations shown in red)

$[X, YZ] = [X, YZ] [Y, Z] = X \cdot YZ \cdot X' \cdot \textcolor{red}{Z'Y'Y'Z} \cdot Y' \cdot Z' = X \cdot YZ \cdot X' \cdot Z'Y'$

$]XY, Z[= [X, Y] [YX, Z] = X \cdot Y \cdot \textcolor{red}{X'Y'YX} \cdot Z \cdot X'Y' \cdot Z' = XY \cdot Z \cdot X'Y' \cdot Z'$

Inverses of semi-commutators

$[X, YZ]' =]ZY, X[$

$]XY, Z]' = [Z, YX]$

4 variables

Expressions of semi-commutators

$[XY, ZP] = XY \cdot ZP \cdot Y'X' \cdot P'Z'$ (commutator)

$[XY, ZP] = XY \cdot ZP \cdot Y'X' \cdot Z'P'$ (semi-commutator)

$]XY, ZP[= XY \cdot ZP \cdot X'Y' \cdot P'Z'$ (semi-commutator)

$]XY, ZP[= XY \cdot ZP \cdot X'Y' \cdot Z'P'$ (semi-commutator)

Semi-commutators as products of 2 or 3 commutators (move cancellations shown in red)

$[XY, ZP] = [XY, ZP] [Z, P] = XY \cdot ZP \cdot Y'X' \cdot \textcolor{red}{P'Z'Z'P} \cdot Z' \cdot P' = XY \cdot ZP \cdot Y'X' \cdot Z'P'$

$]XY, ZP[= [X, Y] [YX, ZP] = X \cdot Y \cdot \textcolor{red}{X'Y'YX} \cdot ZP \cdot X'Y' \cdot P'Z' = XY \cdot ZP \cdot X'Y' \cdot P'Z'$

$]XY, ZP[= [X, Y] [YX, ZP] [Z, P] = X \cdot Y \cdot \textcolor{red}{X'Y'YX} \cdot ZP \cdot X'Y' \cdot \textcolor{red}{P'Z'Z'P} \cdot Z' \cdot P' = XY \cdot ZP \cdot X'Y' \cdot Z'P'$

Inverses of semi-commutators

$[XY, ZP]' =]PZ, XY[$

$]XY, ZP]' = [ZP, YX]$

$]XY, ZP]' =]PZ, YX[$

Semi-commutators may be included in a [brute-force search](#), when searching for algorithms by sweeping variables that take values in a set of basic moves, until swept permutation and goal permutation match, like in this example, where 8 variables are used:

$[XYZPQ, AEG] = XYZPQ \cdot AEG \cdot Q'P'Z'Y'X' \cdot G'E'A'$ (commutator)

$[XYZPQ, AEG] = XYZPQ \cdot AEG \cdot Q'P'Z'Y'X' \cdot A'E'G'$ (semi-commutator)

$]XYZPQ, AEG[= XYZPQ \cdot AEG \cdot X'Y'Z'P'Q' \cdot G'E'A'$ (semi-commutator)

$]XYZPQ, AEG[= XYZPQ \cdot AEG \cdot X'Y'Z'P'Q' \cdot A'E'G'$ (semi-commutator)

Semi-Commutator Example

A short 5-cycle of edge-centers has been obtained from the following semi-commutator:

$$[R \text{ NU}, N3B \text{ R}' \text{ NU} \text{ R} \text{ N3B}'] = R \text{ NU} \text{ N3B} \text{ R}' \text{ NU} \text{ R} \text{ N3B}' \text{ R}' \text{ NU}' \text{ N3B}' \text{ R} \text{ NU}' \text{ R}' \text{ N3B} \text{ (14 moves)}$$

We can search for a shorter algorithm using [Super Cube Solver](http://www.randelshofer.ch/rubik/virtualcubes/vcube7/7x_scripts/7x_super_cube_solver/index_enVE.html) and compare solutions:

$$[N3B', R \text{ NU} \text{ TR}' \text{ F} \text{ NR}] = N3B' \text{ R} \text{ NU} \text{ TR}' \text{ F} \text{ NR} \text{ N3B} \text{ NR}' \text{ F}' \text{ TR} \text{ NU}' \text{ R}' \text{ (12 moves)}$$

Notice that move TR is the combination of moves R and NR, that is: $TR = R \text{ NR}$, thus giving a shorter solution.

SuperCube Solver – Edge-Centers 5-Cycle

http://www.randelshofer.ch/rubik/virtualcubes/vcube7/7x_scripts/7x_super_cube_solver/index_enVE.html

Scramble Algorithm

$$[R \text{ NU}, N3B \text{ R}' \text{ NU} \text{ R} \text{ N3B}'] = R \text{ NU} \text{ N3B} \text{ R}' \text{ NU} \text{ R} \text{ N3B}' \text{ R}' \text{ NU}' \text{ N3B}' \text{ R} \text{ NU}' \text{ R}' \text{ N3B}$$

Solution Algorithm

$$[N3B', R \text{ NU} \text{ TR}' \text{ F} \text{ NR}] = N3B' \text{ R} \text{ NU} \text{ TR}' \text{ F} \text{ NR} \text{ N3B} \text{ NR}' \text{ F}' \text{ TR} \text{ NU}' \text{ R}'$$

Symmetric Commutators

Commutators (or semi-commutators) show structures that are symmetric in nature. If we consider, for example, the following commutator [A, B] of 5 variables [X Y, Z P Q], written as:

$$[A, B] = [X Y, Z P Q] = X Y \cdot Z P Q \cdot Y' X' \cdot Q' P' Z' = (X Y) \cdot (Z P Q) \cdot (X Y)' \cdot (Z P Q)' = A \cdot B \cdot A' \cdot B'$$

we can see that the second half of this expression is simply the composition of the inverses of A and B.

Knowing that a cube has a set of 48 symmetries, we can further expand the concept of this 'plain' commutator to the 'symmetric' commutator, where the inverses of A and B are replaced with As and Bs, being the inverses of their respective transformations by any of the 48 cube symmetries, that is:

$$[A, B]_s = [X Y, Z P Q]_s = X Y \cdot Z P Q \cdot Y_s' X_s' \cdot Q_s' P_s' Z_s' = (X Y) \cdot (Z P Q) \cdot (X_s Y_s)' \cdot (Z_s P_s Q_s)' = A \cdot B \cdot A_s' \cdot B_s'$$

In this notation, subscript 's' indicates that symmetry has been applied to the the second half of the expression.

A plain commutator is then just a particular case of a symmetric commutator, for which the applied symmetry is simply the 'Identity' symmetry:

F → F
R → R
U → U
L → L
D → D
B → B

The concept of symmetric commutators can even be further expanded to symmetric *semi*-commutators as follows:

$$\begin{aligned}]X Y, Z P Q[_s &= X Y \cdot Z P Q \cdot X_s' Y_s' \cdot Z_s' P_s' Q_s' \\]X Y, Z P Q]_s &= X Y \cdot Z P Q \cdot X_s' Y_s' \cdot Q_s' P_s' Z_s' \\ [X Y, Z P Q]_s &= X Y \cdot Z P Q \cdot Y_s' X_s' \cdot Q_s' P_s' Z_s' \end{aligned}$$

It is already known that plain commutators work well in cases where only a few cube pieces are permuted. They are generally of less practical use for solving cube positions with many permuted pieces, though. But, if a scrambled cube shows a symmetric pattern, chances are good that a symmetric commutator could be found that may eventually solve it.

Symmetric Commutator Examples

Symmetric commutators may be used instead of plain commutators in difficult cases, or for finding alternate (symmetric) solution algorithms to already known ones.

As an example, we will search for an alternate algorithm to the hardest distance-20 position of a 3x3x3 cube, using symmetric commutators.

According to the '[God's Number is 20](#)' paper, the following position was the hardest to their programs to solve:

F U' F2 D' B U R' F' L D' R' U' L U B' D2 R' F U2 D2

The algorithm itself doesn't show any obvious symmetry, so we first have to search for symmetric cube positions, if any.

The position shows a symmetry about the F – B axis, so that a half-turn cube rotation (by move CF2) gives another position which is equivalent to the initial one.

Using Cube Explorer 5.00s, all optimal solutions to this algorithm, plus its 19 shifted versions, have been found. From the list, a 18-move algorithm was extracted that presents a symmetric commutator structure:

R' L · D2 U' F' L D U2 F' · L R' · F D2 U' R' F D U2

This algorithm can be rewritten as:

[R' L, D2 U' F' L D U2 F']s

where symmetry CF2 has been applied to the second half, as follows:

F→F
R→L
U→D
L→R
D→U
B→B

Using [Algorithm Finder Lite](#), this 18-move algorithm has been shifted, conjugated and transformed by symmetry to give the following symmetric solutions to the initial (unsymmetric) 20-move algorithm, where SR = R L':

B D' L2 R F D' L' R2 F SU F' L2 R U F' L' R2 U B'
F L' U2 D F L' U' D2 F SR F' U2 D R F' U' D2 R F'
F D' R2 L B D' R' L2 B SU B' R2 L U B' R' L2 U F'
B R' U2 D B R' U' D2 B SR' B' U2 D L B' U' D2 L B'
F' U R2 L' B' U R L2 B' SU B R2 L' D' B R L2 D' F
B' R D2 U' B' R D U2 B' SR B D2 U' L' B D U2 L' B
B' U L2 R' F' U L R2 F' SU F L2 R' D' F L R2 D' B
F' L D2 U' F' L D U2 F' SR' F D2 U' R' F D U2 R' F

Symmetric Commutator – Example 1

Unsymmetric Algorithm	Symmetric Algorithm (s = CF2)
F U' F2 D' B U R' F' L D' R' U' L U B' D2 R' F U2 D2	F' L D2 U' F' L D U2 F' SR' F D2 U' R' F D U2 R' F

Symmetric commutators may also be used for permuting a few cube pieces, although plain commutators will generally provide shorter solutions, as shown below for the case of corner-center 5-cycle.

Symmetric Commutators [NR, NU' NR NU R]s (10 moves) [NR, ND' NR' ND D2]s (10 moves)		Commutators NF' D NF ND' NF' D' NF' ND NF2 (9 moves) U D NR' ND' NR U' D' NR ND NR' (10 moves)
